

**The value of anti-Müllerian hormone measurement  
in the long GnRH agonist protocol:  
association with ovarian response  
and gonadotrophin dose adjustments**

Human Reproduction, Vol.27, No.6 pp. 1829-1839, 2012

指導：蔡永杰主任

報告：R 2 闕貝如

# Introduction

## AMH(anti-Müllerian hormone)

- a glycoprotein belonging to the transforming growth factor- $\beta$  superfamily (Cate et al, 1986)
- In women, produced solely by the ovarian granulosa cells
  - low in primary follicles but increases to maximal levels in pre-antral and small antral follicles (up to 6–7 mm in diameter)
  - gradually declines as follicles increase further in size
  - becomes undetectable at a stage where FSH-dependent follicular growth has been initiated
  - not expressed in atretic follicles

# Introduction

## AMH (anti-Müllerian hormone)

# Introduction

## AMH (anti-Müllerian hormone)

- plays a role in the control of follicle growth via paracrine and autocrine effects
- inhibits the recruitment of resting follicles from the primordial follicle pool (Durlinger et al., 1999; Carlsson et al., 2006)
- decreases the sensitivity of small antral follicles to FSH (Durlinger et al., 2001)

# Introduction

## AMH (anti-Müllerian hormone)

- The serum level of AMH is a marker of the **ovarian reserve**
- the number of *antral follicles* has been shown to correlate more strongly with serum AMH than with the serum level of FSH (Fanchin et al., 2003a)
- AMH appears to be the earliest endocrine marker of **ovarian aging** (de Vet et al., 2002)

# Introduction

## AMH (anti-Müllerian hormone)

- The serum AMH level shows only minimal fluctuations during the menstrual cycle (La Marca et al., 2006)
  - reflecting the continuous noncyclic growth of pre-antral and small antral follicles (independent of FSH)
- the serum level of AMH displays a high inter-cycle Reproducibility
  - a single blood sample is sufficient for a reliable assessment of the ovarian reserve, compared with three measurements for FSH (Fanchin et al., 2005)

# Introduction

## AMH (anti-Müllerian hormone)

- AMH to be superior to the age of the patient and measurements of FSH, estradiol and inhibin B on cycle day 2–3 in predicting oocyte yield in IVF (La Marca et al., 2010)
- serum AMH levels have been demonstrated to decrease gradually during the follicular phase in both pituitary-desensitized GnRH agonist cycles (Fanchin et al., 2003b; La Marca et al., 2004) and GnRH antagonist cycles (Lee et al., 2010)

# Materials and Methods : study population

- retrospective analysis of data derived from a randomized, active-controlled, assessor-blind, multicentre, multinational trial
- patients (n = 731) undergoing IVF after stimulation with
  - hMG (Menopur; Ferring Pharmaceuticals A/S, Copenhagen, Denmark)
  - rFSH (follitropin alfa, Gonal-F; Merck Serono, Geneva, Switzerland)

# Materials and Methods : study population

- Inclusion criteria
  - tubal factor infertility
  - unexplained infertility
    - endometriosis stage I/II
    - mild semen abnormalities not requiring ICSI
  - Age : 21 ~ 37
  - BMI : 18~29 kg/m<sup>2</sup>
  - FSH within normal limits (1-12 IU/L)
  - Regular menstrual cycles of 21-35 days which were presumed to be ovulatory and a willingness to accept transfer of one or two embryos.

# Materials and Methods : study population

- Exclusion criteria
  - polycystic ovary syndrome
  - endometriosis stage III/IV
  - partners with severe male factors requiring ICSI

# Materials and Methods : study protocol

- Patients underwent COS following down-regulation with a GnRH agonist in a long protocol
- Pituitary suppression (triptorelin acetate, 0.1 mg/day S.C. ) was initiated 5–7 days before the estimated start of next menses and continued until the end of gonadotrophin administration
- Prior to start of ovarian stimulation, the antral follicle count (AFC; follicles <2 mm ) was recorded by TVU of the ovaries by one or more operators at the clinics and follicular development was monitored after 5 days of treatment and thereafter at least every 2 days

# Materials and Methods : study protocol

- Stimulation with HP-hMG or rFSH was started at a dose of 225 IU /day for the first 5 days and was followed by individual dose-adjustments according to the patient's follicular response as exclusively measured by TVU .
- The daily dose could either be increased or decreased by 75 IU per adjustment and not changed more frequently than every fourth day .
- Recombinant hCG (choriogonadotrophin alfa, Ovitrelle ; Merck Serono ), 250 mg S.C ., was used to induce final follicular maturation when  $\geq 3$  follicles of  $\geq 17$  mm in diameter were observed and was administered  $36 \pm 2$  h before planned oocyte retrieval .

# Materials and Methods : study protocol

- The target for the ovarian stimulation was set to be 7–15 oocytes
  - reasonable chances (25% ) of pregnancy
  - the risk of developing moderate /severe ovarian hyperstimulation syndrome (OHSS ) is low in patients with  $\leq 15$  oocytes (Arce et al., 2005 )
- Cycle cancellation :
  - at the day of hCG administration were either
    - inability to reach the hCG criterion, or
    - $>25$  follicles with a diameter of  $\geq 10$  mm

# Materials and Methods : study protocol

- A top-quality embryo (TQE) was defined as
  - 4~5 cells on Day 2,
  - $\geq 7$  cells on Day 3, equally-sized blastomeres and  $\leq 20\%$  fragmentation on Day 3 and no multinucleation
- The transfer of one or two embryos was done on Day 3 after oocyte retrieval

# Materials and Methods : study protocol

- Vaginal progesterone gel of 90 mg/day 8%
  - for luteal support
  - from the day of embryo transfer
  - until the confirmation of clinical pregnancy (5–6 weeks after embryo transfer) or negative serum hCG test (13–15 days after embryo transfer)

# Materials and Methods :

## Collection and handling of serum

- Blood samples for AMH : Days 1 ,6 and the last day of stimulation, the day of oocyte retrieval.
- Day 1 : before the start of gonadotrophin administration
- Day 6 and last stimulation day: at least 8 h after the previous gonadotrophin dose.
- Centrifuged : 10 min, 1800g.
- Stored : at -18C or colder at the clinic for a maximum of 2 weeks before transfer to -70C and subsequent analysis at a central laboratory.
- The sera were only thawed once.

# Materials and Methods :

## Collection and handling of FF

- patients who had oocyte retrieval.
- Fluid was collected from one follicle of  $\geq 7$  mm from which an oocyte was retrieved.
- Fluid was preferably collected from **the first follicle** aspirated and from follicles where flushing had not been performed.
- Centrifuged : 10 min, 1000g .
- Fluids that were found to be contaminated by RBC or flushing medium were not included.

# Analytical methods for the variables measured in serum and FF

- Serum and FF AMH analysis was performed batch wise in a single laboratory (hormone laboratory at Universitair Ziekenhuis, Brussels) to minimize variability
- AMH was measured with the Immunotech Beckman Coulter AMH ELISA kit (A11893)
- The intra-assay and inter-assay coefficients of variation were ,9.5%
- Functional sensitivity of the assay was 2.5 pmol/l  
(1 ng/ml = 7.14 pmol/l)

# Analytical methods for the variables measured in serum and FF

- Serum was analysed for other endocrine variables by a central laboratory using
  - electrochemiluminescence immunoassays
    - FSH, LH, hCG
  - chemiluminescent immunometric assays
    - estradiol, progesterone, SHBG
  - radioimmunoassays
    - androstenedione, total testosterone

# Analytical methods for the variables measured in serum and FF

- The sensitivity [and total imprecision (coefficient of variation, CV)] of the validated analytical methods were as follows
  - FSH ,0.1 IU/l (,6% ),
  - LH ,0.1 IU/l (,6% ),
  - hCG ,0.1 IU/l (,8% ),
  - estradiol 55 pmol/l (10% ),
  - Progesterone 0.6 nmol/l (,8% ),
  - SHBG 0.02 nmol/l (10% ),
  - Androstenedione 0.08 nmol/l (10% )
  - Total testosterone 0.17 nmol/l (5% )

# Analytical methods for the variables measured in serum and FF

- The sensitivity (and total imprecision, CV) were as follows:
  - FSH, 0.1 IU/l (5%),
  - LH 0.1 IU/l (5%),
  - hCG, 0.1 IU/l (8%),
  - estradiol 18 pmol/l (5%),
  - Progesterone 0.095 nmol/l (5%),
  - SHBG 0.35 nmol/l (5%),
  - Androstenedione 0.13 nmol/l (12%),
  - total testosterone 0.1 nmol/l (8%),
  - cortisol 20 nmol/l (8%),
  - cortisone 4 nmol/l (10%),
  - inhibin A 1.0 ng/l (9%),
  - VEGF, 9.0 ng/l (7%)
  - IGF-1 0.105 nmol/l (10%)

# Results

## Serum AMH at the start of the stimulation

- 731 patients who initiated COS
  - 623 patients had serum AMH measurements on stimulation day 1
    - 314 patients treated with HP-hMG
    - 309 patients treated with rFSH

**Table 1 Patient demographics, baseline characteristics and serum endocrine concentrations at the start of the stimulation.**

Variable	All <sup>a</sup> (n = 623)	HP-hMG <sup>a</sup> (n = 314)	rFSH <sup>a</sup> (n = 309)
Baseline			
Age (years), mean (SD)	30.8 (3.3)	30.8 (3.2)	30.8 (3.4)
Weight (kg), mean (SD)	62.1 (8.4)	62.8 (8.5)	61.3 (8.3)
BMI (kg/m <sup>2</sup> ), mean (SD)	22.3 (2.6)	22.5 (2.7)	22.1 (2.6)
Duration of infertility (years), mean (SD)	3.9 (2.2)	3.9 (2.3)	3.9 (2.2)
Primary cause of infertility			
Tubal infertility, n (%)	213 (34%)	116 (37%)	97 (31%)
Mild male factor, n (%)	59 (9%)	29 (9%)	30 (10%)
Other (incl. endometriosis I/II), n (%)	65 (10%)	31 (10%)	34 (11%)
Unexplained infertility, n (%)	286 (46%)	138 (44%)	148 (48%)
Duration of GnRH agonist before the start of stimulation (days)	15.1 (4.0)	15.1 (4.1)	15.1 (3.9)
Day 1 of stimulation			
Mean ovarian volume (ml)	4.3 (3.0, 5.9)	4.4 (3.1, 5.9)	4.3 (2.9, 5.9)
AFC			
21–29 years	11 (7, 16); n = 209	11 (8, 16); n = 105	10 (7, 16); n = 104

Values are median (IQR) unless otherwise indicated.

<sup>a</sup>Patients with AMH measurement at the start of stimulation.

# Results

## Serum AMH at the start of the stimulation

Correlation :

- Negative : between serum AMH at the start of the stimulation / age (  $r = -0.25$  )
- Positively : AFC (  $r = 0.35$ ,  $P < 0.001$  )
- Weak :
  - age / AFC (  $r = -0.08$ ,  $P = 0.046$  )
  - (  $r \leq 0.15$  ) at the start of the stimulation between Serum AMH and serum concentrations of FSH, LH, estradiol, progesterone, androstenedione, SHBG, total testosterone and free androgen index.

# Results

## Serum AMH during the stimulation

- The serum AMH concentration decreased gradually during COS and showed similar dynamic changes in both treatment groups, although a significantly ( $P < 0.001$ ) larger reduction was noted during stimulation with rFSH than with HP-hMG.

# Results

## Serum AMH during the stimulation

- The median AMH (IQR) concentration was decreased
  - In the rFSH group,
    - 30% to 18.6 (12.8, 27.5) pmol/l on Day 6 of stimulation
    - 55% to 11.9 (8.1, 16.9) pmol/l on the last day of stimulation
  - In the HP-hMG group
    - 16% to 21.4 (14.9, 32.7) pmol/l on Day 6
    - 46% to 13.7 (10.3, 19.6) pmol/l on the last day of stimulation in the HP-hMG group.

# Results

## Serum AMH during the stimulation

- Day 1 , Day 6 and the last day of stimulation ( $p < 0.001$ )
  - HP -hM G group:  $r = 0.91$  and  $0.82$
  - rF S H group:  $r = 0.93$  and  $0.84$
- The magnitude of the decreases in serum AMH from baseline to stimulation day 6 as well as during the whole stimulation period was correlated ( $P < 0.001$ ) with the number of follicles  $\geq 10$  mm on Day 6 and on the last stimulation day
  - HP -hM G group:  $r = 0.33$  and  $0.51$
  - rF S H group:  $r = 0.38$  and  $0.57$

# Results

## Serum AMH association with endocrine values

- AMH concentrations at the start of stimulation
  - Serum estradiol and androstenedione on Day 6 (P, 0.001)
    - HP-hMG group:  $r = 0.38$  and  $0.31$ , respectively
    - rFSH group:  $r = 0.58$  and  $0.34$ , respectively
  - the last stimulation day and on the day of oocyte retrieval respectively, of serum estradiol
    - HP-hMG group:  $r = 0.45$  and  $0.49$ , respectively
    - rFSH group:  $r = 0.55$  and  $0.53$ , respectively

# Results

## Serum AMH association with

### endocrine values

- androstenedione
  - HP -hM G group:  $r = 0.50$  and  $0.52$ , respectively;
  - rFSH group:  $r = 0.49$  and  $0.49$ , respectively ),
- total testosterone
  - HP -hM G group:  $r = 0.40$  and  $0.44$ , respectively;
  - rFSH group:  $r \frac{1}{4} 0.36$  and  $0.39$ , respectively )
- The serum progesterone concentration
  - at oocyte retrieval was also significantly ( $P , 0.001$  ) correlated with serum AMH measured at the start of the stimulation
    - HP -hM G group:  $r = 0.39$ ; rFSH group:  $r = 0.50$  )

# Results

## Serum AMH association with endocrine values

- Correlations between serum AMH at the start of the stimulation and all other endocrine variables in serum measured on Day 6 or at the end of the stimulation were
- $<0.30$ .
- Similar relationships between AMH and endocrine variables were observed when using AMH concentrations on Day 6 or at the end of stimulation instead of AMH at the start of the stimulation

# Results

## Serum AMH association with ovarian response

- The median (IQR) number of oocytes retrieved was significantly ( $P, 0.001$ ) higher in the rFSH group compared with the HP-hMG group: 11 (8, 16) versus 9 (6, 13).
- The serum concentrations of AMH on stimulation days 1, 6 and last day were all significantly ( $P, 0.001$ ) positively correlated with the number of oocytes retrieved. In both treatment groups, the correlations were stronger for basal AMH (HP-hMG:  $r = 0.48$ ; rFSH:  $r = 0.62$ ) than for AMH on Day
- 6 (HP-hMG:  $r = 0.42$ ; rFSH:  $r = 0.58$ ) or AMH on the last
- day (HP-hMG:  $r = 0.35$ ; rFSH:  $r = 0.48$ )

# Results

## Serum AMH association with outcome

- Lorem ipsum dolor sit amet, consectetur adipiscing elit. Vivamus et magna. Fusce sed sem sed magna suscipit egestas.
- Lorem ipsum dolor sit amet, consectetur adipiscing elit. Vivamus et magna. Fusce sed sem sed magna suscipit egestas.

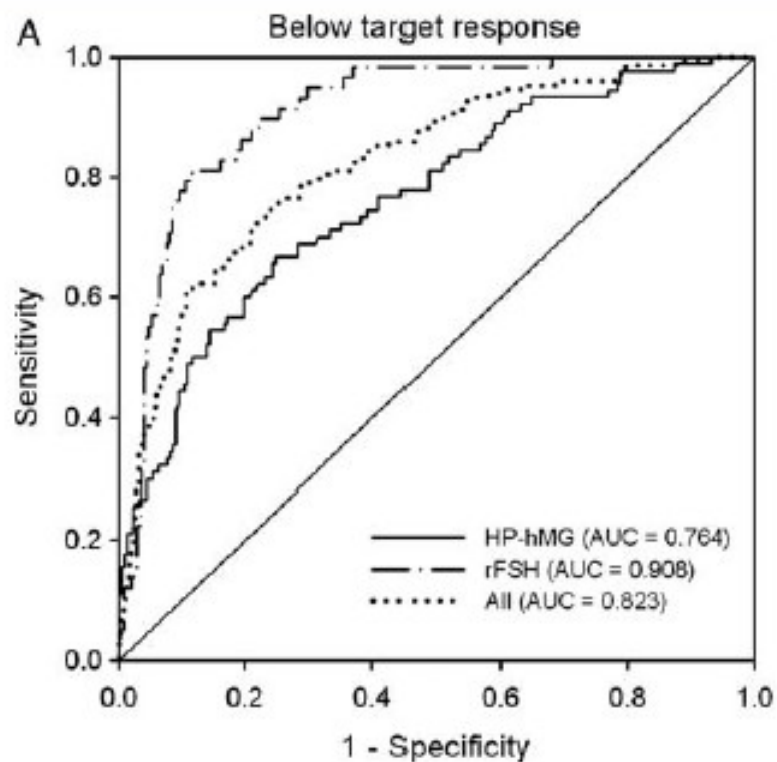

# Discussion

- The lower decline in serum AMH and the higher AMH concentration in FF at oocyte retrieval in the HP-hMG group compared with the rFSH group can be readily explained by the less pronounced follicle growth observed during the initial stimulation and the lower number of follicles/oocytes retrieved after stimulation with HP-hMG

# Discussion

- The stronger correlation between serum AMH at the start of the stimulation and the serum estradiol concentration on stimulation day 6 in the rFSH group compared with the HP-hMG group may reflect the early estrogenization of a larger fraction of follicles recruited in the rFSH group

**Figure 1** ROC curve analysis showing the predictive value of serum AMH at the start of the stimulation for the estimation of number of oocytes at retrieval below ( $<7$ ) (A) and above ( $>15$ ) the target (B) after COS in patients treated with HP-hMG or rFSH in the long GnRH agonist protocol. The diagonal line is the reference line of no discrimination (AUC = 0.5). Cut-off values for response below the target were 21.2 pmol/l for HP-hMG (sens. 66.7%, spec. 75.2%) and 16.4 pmol/l for rFSH (sens. 81.0%, spec. 88.3%). The cut-off values for response above the target were 29.8 pmol/l for HP-hMG (sens. 73.3%, spec. 67.0%) and 29.5 pmol/l for rFSH (sens. 82.5%, spec. 70.4%).

**Table II** Baseline, stimulation and outcome variables grouped by AMH quartiles at the start of the stimulation.

Variable	AMH quartiles												P-value (AMH)	P-value (treatment)
	<P25 <sup>a</sup>			P25–P50 <sup>b</sup>			>P50–P75 <sup>c</sup>			>P75 <sup>d</sup>

Within target (7–15 oocytes), n (%)	60 (39)	26 (36)	34 (41)	109 (70)	57 (66)	52 (74)	93 (60)	48 (61)	45 (58)	83 (55)	46 (61)	37 (48)		
Above target (>15 oocytes), n (%)	2 (1)	1 (1)	1 (1)	15 (10)	7 (8)	8 (11)	45 (29)	14 (18)	31 (40)	63 (41)	23 (31)	40 (52)		
TQEs <sup>f</sup>	0.6 (0.9)	0.5 (0.9)	0.7 (1.0)	0.9 (1.3)	1.0 (1.1)	0.9 (1.5)	1.1 (1.6)	1.0 (1.4)	1.2 (1.7)	1.4 (2.1)	1.5 (2.3)	1.3 (2.0)	<0.001 <sup>g</sup>	0.830 <sup>g</sup>
TQE/OR (%) <sup>f</sup>	8.6 (14.9)	8.4 (16.5)	8.8 (13.5)	9.5 (13.2)	10.9 (13.5)	7.8 (12.7)	9.3 (11.9)	9.9 (12.5)	8.6 (11.3)	10.2 (15.0)	11.9 (17.3)	8.4 (12.1)	0.290 <sup>g</sup>	0.094 <sup>g</sup>
Ongoing pregnancy, n (%)	29 (19)	9 (12)	20 (24)	52 (33)	26 (30)	26 (37)	39 (25)	26 (33)	13 (17)	41 (26)	25 (33)	16 (20)	0.915 <sup>h</sup>	0.374 <sup>h</sup>

<sup>a</sup><16.8 pmol/l.

<sup>b</sup>16.8–26.0 pmol/l.

<sup>c</sup>26.1–37.4 pmol/l.

<sup>d</sup>>37.4 pmol/l.

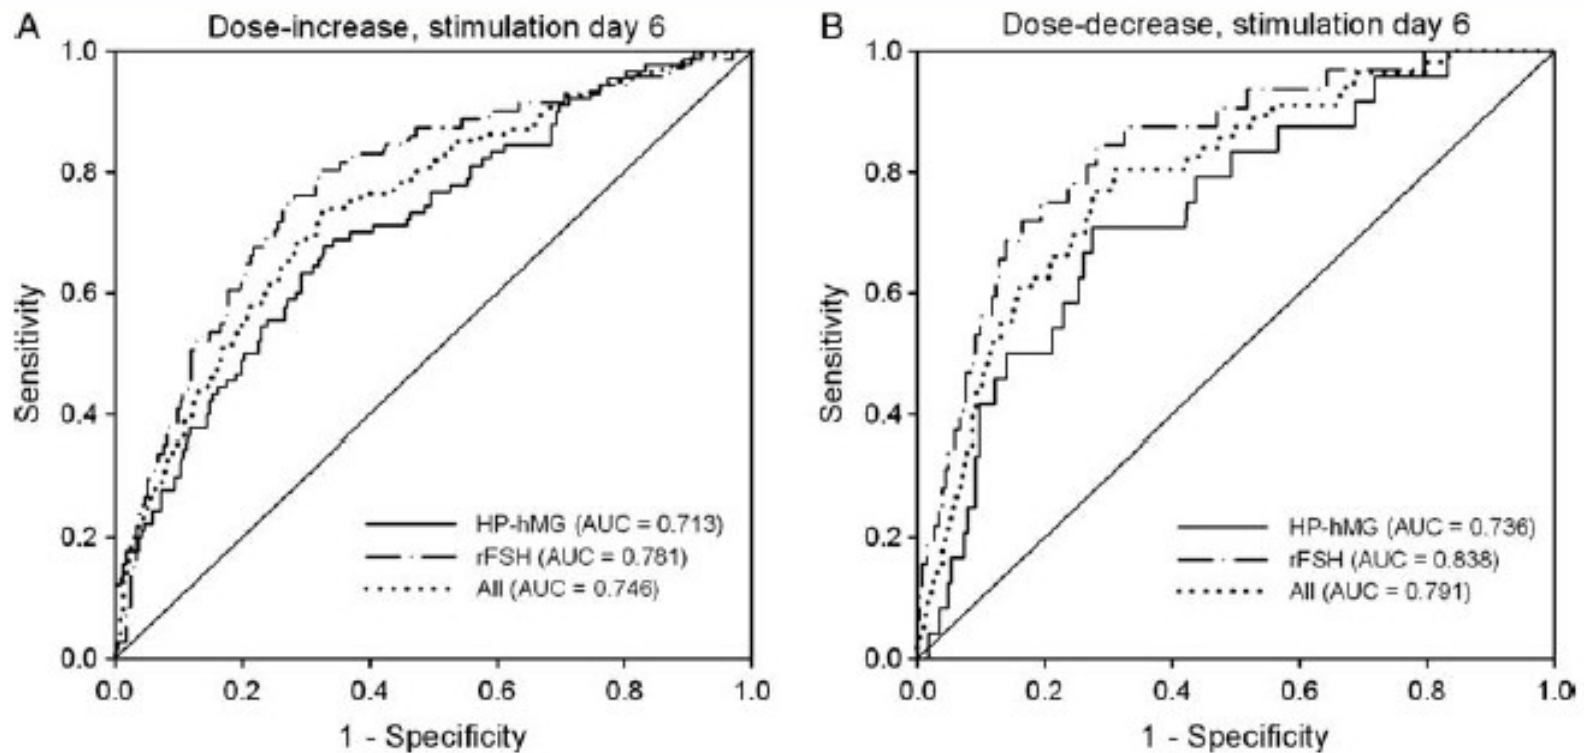

<sup>e</sup>Median (IQR).

<sup>f</sup>Mean (SD).

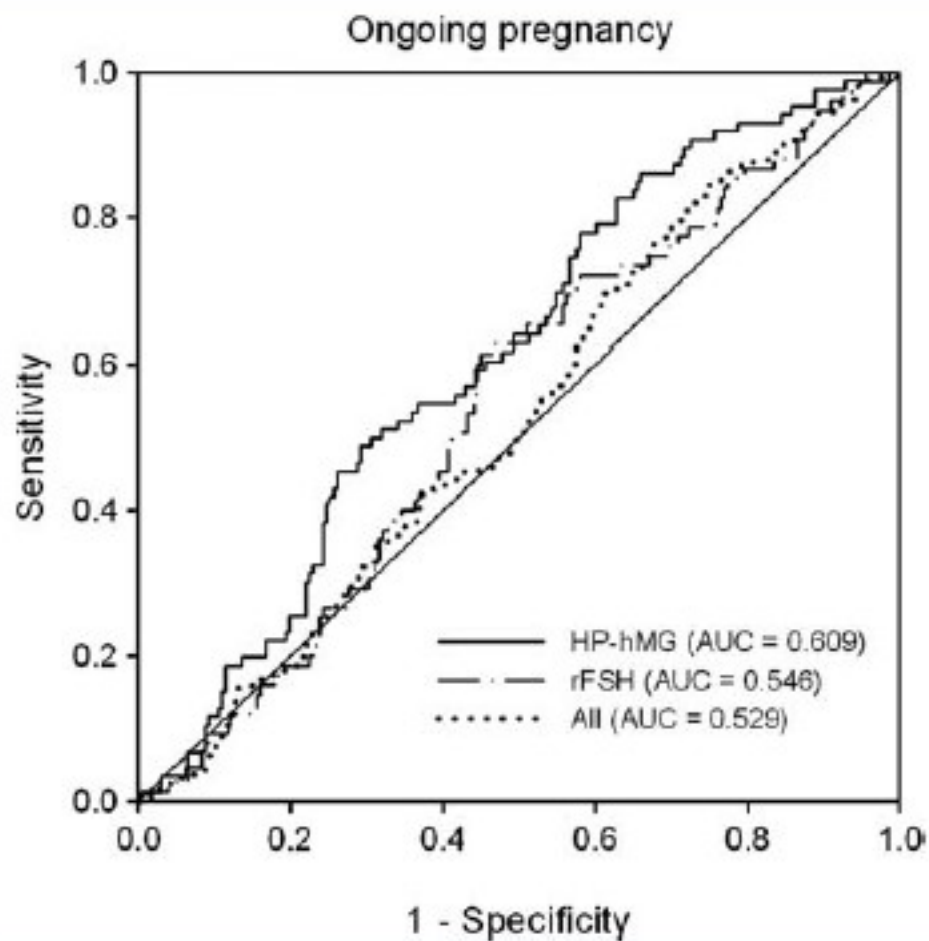

<sup>g</sup>ANCOVA.

<sup>h</sup>Logistic regression.

# Discussion

**Figure 2** ROC curve analysis showing the predictive value of serum AMH at the start of the stimulation for the need for a gonadotrophin-dose increase (A) or decrease (B) on stimulation day 6 in patients treated with HP-hMG or rFSH in the long GnRH agonist protocol. All patients had received starting doses of 225 IU/day for the first 5 days. The diagonal line is the reference line of no discrimination (AUC = 0.5). Cut-off values for increased dose were 23.0 pmol/l for HP-hMG (sens. 67.8%, spec. 67.1%) and 21.4 pmol/l for rFSH (sens. 74.6%, spec. 73.6%). The cut-off values for decreased dose were 32.4 pmol/l for HP-hMG (sens. 70.8%, spec. 72.6%) and 37.4 pmol/l for rFSH (sens. 75.0%, spec. 80.7%).

**Figure 3** ROC curve analysis showing the predictive value of serum AMH at the start of the stimulation for ongoing pregnancy in patients treated with HP-hMG or rFSH in the long agonist protocol. The diagonal line is the reference line of no discrimination (AUC = 0.5).
